37 Abstract

38

Phytoplasma associated diseases are reported for more than a thousand plant species
worldwide. Only a few genome sequences are available in contrast to the economical
importance of these bacterial pathogens.

42 A new strategy was used to retrieve phytoplasma strain-specific genome data. Multiple 43 displacement amplification was performed on DNA obtained from less than three grams of 44 plant tissue from tobacco and parsley samples infected with stolbur strains. Random hexamers 45 and Phi29 polymerase were evaluated with and without supplementation by group-assigned 46 oligonucleotides providing templates for Illumina's sequencing by synthesis approach. 47 Metagenomic drafts derived from individual and pooled strain-specific de novo assemblies 48 were analysed. Supplementation of the Phi29 reaction resulted in an about 2-fold enrichment 49 of the percentage of phytoplasma assigned reads and thereby improved assembly results. The 50 obtained genomic drafts represent the largest data sets available from 'stolbur' phytoplasmas. 51 Sequences of the two strains (558 kb, 448 proteins and 516 kb, 346 proteins, respectively) 52 were annotated allowing the identification of prominent membrane proteins and 53 reconstruction of core pathways. Analysis of a putative truncated sucrose phosphorylase 54 provides hints on sugar degradation. Furthermore, it is shown that drafts obtained from 55 repetitive-rich genomes allow only limited analysis on multi-copy regions and genome 56 completeness.

57

58 Key Words: 'stolbur' phytoplasma, MDA, metagenome analysis, metabolism

59 Introduction

60

61 Phytoplasmas are bacterial pathogens infecting plant and insects. They are associated with 62 diseases in several hundred plant species including many important crops [McCoy et al., 63 1989]. Recently, more than 30 species have been assigned to the provisory taxon 'Candidatus' 64 Phytoplasma' in the phylum *Tenericutes* [Kube et al., 2012]. The assignment as a candidate 65 clade reflects the resistance of phytoplasmas to attempts of a cell-free cultivation in the past, 66 which so far also slowed down genome research in phytoplasma; however a first cell-free 67 cultivation of phytoplasma strains was recently reported for a few strains [Contaldo et al., 68 2012]. 69 As a result of their evolutionary adaptation to intracellular life in plants and insects 70 phytoplasmas have small genomes encoding a minimal metabolism [Kube et al., 2012; 71 Oshima et al., 2004]. Only four complete genomes were determined so far encompassing 72 'Candidatus Phytoplasma asteris' strains OY-M (853 kb) and AY-WB (707 kb), 'Ca. P. 73 australiense' (880 kb), and 'Ca. P. mali' (602 kb) [Bai et al., 2006; Kube et al., 2008; Oshima 74 et al., 2004; Tran-Nguyen et al., 2008]. Recently, the draft genomes of vaccinium witches' 75 broom phytoplasma (647,754 nt in 272 contigs), Italian clover phyllody phytoplasma strain 76 MA (597,245 nt in 197 contigs), poinsettia branch-inducing phytoplasma strain JR1 (631,440 77 nt in 185 contigs) and milkweed yellows phytoplasma (583,806 nt in 158 contigs) were 78 published [Saccardo et al., 2012]. Phytoplasma-genome data were used for downstream 79 experiments ranging from the design of PCR primers for marker genes and/or strain 80 differentiation [Neriva et al., 2011; Seemüller et al., 2011] to the identification of effectors changing the plant phenotype [Hoshi et al., 2009; Sugio et al., 2011]. Genome sequences also 81 82 allow the bioinformatical reconstruction of the major pathways in phytoplasmas [Kube et al., 83 2012].

84 This study deals with 'stolbur' phytoplasmas, which are infecting a wide range of cultivated 85 and wild plants [Garnier, 2000]. This phytoplasma now classified as 'Ca. P. solani' [Quaglino 86 et al., 2013], together with closely related 'Ca. P. australiense', belongs to 16S ribosomal 87 group XII [IRPCM, 2004]. Some very important plant diseases and severe crop losses are 88 associated with this phytoplasma such as 'bois noir' on grapevine, corn reddening and stolbur 89 of solanaceous plants. 'Stolbur' disease was first described in Serbia starting in 1949 and 90 since then it has been reported in many cultivated crops and ornamental plants as well as in 91 wild plant species and its vectors. First insights on the genetic information encoded by 92 'stolbur' phytoplasma were provided by sequencing clones derived from amplified DNA 93 enriched by double suppression subtractive hybridization (SSH) from *Catharanthus roseus* L. 94 infected with strain PO. Cimerman and colleagues (2006) determined 181 sequences 95 representing 113,209 nucleotides encoding 194 coding sequences of their estimated 820-850 96 kb sized genome. Despite this chromosome size estimation, loss of larger genome fragments 97 during the propagation in infected plant hosts is described [Brown et al., 2007] and may also 98 indicate the occurrence of smaller chromosomes in nature. The impact of horizontally 99 transferred genetic material [Kube et al., 2012; Wei et al., 2008], transposon-mediated gene 100 duplication [Bai et al., 2006] or group II intron [Cimerman et al., 2006] on these processes 101 cannot be estimated for 'stolbur' phytoplasmas so far. 102 Since the major problem for studying phytoplasmas in its original hosts is the low 103 concentration of pathogen in infected plants [Tran-Nguyen and Gibb, 2007] the enrichment of 104 phytoplasma DNA or depletion of host genomic DNA is a critical step. Several approaches 105 were used with pulsed field gel electrophoreses and gradient centrifugation being the most 106 successful strategies applicable to many different types of starting material [Cimerman et al., 107 2006; Jiang et al., 1988; Seddas, 1993]. PFGE technique provides the highest DNA quality 108 with respect to the purity [Tran-Nguyen and Gibb, 2007]. However, caesium chloride (CsCl) 109 buoyant gradient centrifugation [Kollar et al., 1990] is one of the most commonly used

110 method to enrich phytoplasma DNA. Other methods such as suppression SSH e.g. in 111 combination with mirror orientation selection result in a selected amplification of 112 extrachromosomal DNA [Tran-Nguyen and Gibb, 2007] or for a doubled SSH in a biased 113 representation of the chromosome [Yilmaz et al., 2010]. Isothermal amplification using Phi29 114 DNA polymerase was also used to obtain high quantities of phytoplasma DNA from low 115 amount templates [Tran-Nguyen and Gibb, 2007] since this system mediates whole genome 116 amplification (WGA) from single cells [Hosono et al., 2003; Spits et al., 2006]. It is 117 characterised by its strand displacement activity and its impressive processivity in a highly accurate manner [Esteban et al., 1993]. Amplicons of more than 70,000 nt can be produced 118 119 [Blanco et al., 1989]. The technical application of this enzyme was introduced by the rolling 120 circle amplification (RCA) using random primers [Dean et al., 2001; Lizardi et al., 1998]. 121 This approach was improved by the introduction of thiophosphate-modified random hexamers 122 [Dean et al., 2002] and renamed multiple displacement amplification (MDA) taking into 123 account that also linear products are amplified. Consequently, MDA was used in combination 124 with target-specific primers for diagnostic purposes [James et al., 2011; Xu et al., 2008]. 125 Here, we present a new MDA-based strategy to obtain DNA templates for deep sequencing, 126 which was used to generate annotated genomic draft sequences of two 'stolbur' strains from 127 naturally infected tobacco and parsley.

- 129

130 **Experimental Procedures**

An overview of the workflow of the experiment carried out is given in figure 1 including key steps such as data generation, analysis of the metagenomic data, calculation of a potential enrichment by selected oligomers, analysis of the deduced protein content of the two strains, determination of the *sucP* transcript, comparison of the gene content of different strains and limits resulting from the sequencing of repeat-rich genomes in the assembly.

137 DNA extraction and initial enrichment

Two 'stolbur' strains from Northern Serbia were used: 284/09 originated from tobacco plant collected in Ečka in September 2009, grafted to tobacco seedling and maintained in micropropagation. On this sample Dellaporta enrichment [Dellaporta et al., 1983] was used followed by CTAB extraction [Ahrens and Seemüller, 1992]. Stolbur strain 231/09 originated from parsley plant (*Petroselinum sativum*) collected in Pančevo in October 2009 was the second one, and for it CTAB extraction and no initial enrichment were used. Half a gram of starting material was used for strain 231/09 and less than 3 g for 284/09.

145

146 MDA control experiments

The Illustra GenomiPhi DNA amplification kit V2 (GE Healthcare, Munich, Germany) was used for all Phi29 based amplifications in this study. Amplification and subsequent purification (Qiagen clean-up recommendations for repli-G products: www.qiagen.com) was performed according to the manufacturer's instructions for a reaction volume of 20 μl without modifications (control experiments). One reaction for DNA templates obtained from parsley infected with 231/09 and one for tobacco infected with 284/09 was set up for comparison.

153

154 Calculation of oligomers for the use of enrichment oligonucleotides

Random hexamers and/or oligonucleotides corresponding to highly frequent oligomers encoded in the phytoplasma genomes were used for DNA amplification. Oligomers were calculated on a sequence concatamer consisting of the four complete chromosomes of '*Ca*. P. asteris' strains AY-WB (CP000061) and OY-M (AP006628), '*Ca*. P. mali' (CU469464) and '*Ca*. P. australiense' (AM422018). The obtained phytoplasma concatamer was divided by a Perl (http://www.perl.org/) script into 102 windows with a size of about 30 kb. All possible 21mers in each respective window were calculated and counted using a sliding window

162 approach. Selected oligomers correspond to the used oligonucleotides within the next steps. 163 Oligomer sequence and its appending count of the respective window were saved with the 164 help of a hash during processing and sorted by their count. To reduce calculation time and 165 storage space only the 100,000 most frequently oligomers for each window were saved. 166 Oligomers sequences were excluded, if they do not contain two bases of cytosine, two bases 167 of guanine or one base of guanine and one base of cytosine at least. This step was performed 168 to increase the specificity. Most frequently encoded oligomers were determined and a 169 minimal set of 28 oligomers (21 bases in length each) was selected covering 95% of the 170 concatamer, if product size of 30 kb is assumed. The set of enrichment oligonucleotides 171 (Eurofins MWG Synthesis GmbH, Ebersberg, Germany) consists of: 172 5'-GATAATTTCATATCTTTTCAA-3', 5'-TTTTTAAAAATTCTTTAAGACT-3', 5'-TTTTTTGGAAAAAATGTTGT-3', 5'-ATTCAATTAAATTTAATAAAC-3', 173 174 5'-ACACTTAGATGCTTTCAGTGT-3', 5'-CTGTTTCATTTATTTAGACAA-3', 175 5'-TTTGAAAAGATATGAAATTAT-3', 5'-TATTTATATCGATCTTTTTT-3', 176 5'-AAAGATATGGAAATATCTAAT-3', 5'-TTTTCATTTGGTTCATTTTT-3', 177 5'-GGACATTTAATTTCTAATAAA-3', 5'-TATTAAAAACTAAAATATCGA-3', 178 5'-TACAAACGTGATACAATGGCT-3', 5'-TTAAAATGGCGAGAAATTACA-3', 179 5'-AATTTTTAAATCAAAAAATGT-3', 5'-GAAATGCTTAAATTAGCTGAT-3', 180 5'-TTATCATGAAGCAGGACATGC-3', 5'-TATTGATAAATTTTATAAGGA-3', 181 5'-TGACTCCTCAATTAGAAGAAC-3', 5'-CGTTTGAGAAGGGATTCGAAC-3', 182 5'-ACTAAATTGTTTATTAAAAAA-3', 5'-GTTCGAATCCCTTCTCAAACG-3', 183 5'-AAAATCATATTGATATAATAA-3', 5'-ACGTAATGTTATTTTAGAAAA-3', 184 5'-TGTCTAAGAAAAAATTATTT-3', 5'-ATTATATCAATATGATTTTTA-3', 185 5'-GTTAAAAATTAACCATTTATT-3', 5'-AATCAAAAAAATAATAAGGAG-3'.

186

187 MDA using phytoplasma enrichment oligonucleotides

Amplification and subsequent purification was performed according to the manufacturer's instructions with some modifications. Phi29 reaction volumes were supplemented by additional oligonucleotides increased by 1 μ l to a final reaction volume of 21 μ l. The set of enrichment oligonucleotides (100 pmol each) was added to the reaction mix including the random hexamers. The set of enrichment oligonucleotides is present in a final concentration of 0.4 μ M. Experiments were performed for both strains.

- 194
- 195 MDA using group-specific oligonucleotides

196 In an independent control experiment P1/P7 primers [Deng and Hiruki, 1991; Smart et al., 197 1996] were used in different concentrations in combination with random hexamers. The three 198 experiments contain P1/P7 primer with a final concentration of 0.4 μ M, 3.3 μ M and 5.5 μ M. 199 Experiments were carried out on tobacco sample infected with strain 284/09.

The experiment with the highest primer supplement were carried out using primers and DNA template vacuum dried in a speedvac (Savant, Farmingdale, NY, U.S.A.) and resuspended in the sample buffer of the illustra GenomiPhi DNA amplification kit V2 (GE Healthcare, Munich, Germany) for 30 minutes to keep equal reaction volumes.

- 204
- 205 Sequencing by synthesis
- 206 About 3-5 µg of each MDA product was used for library preparation from Illumina
- 207 sequencing. Barcoded libraries were prepared using the NEBnext DNA sample prep Kit (New
- 208 England Biolabs, Ipswich, Massachusetts, U.S.A.) according to manufacturer's instructions.
- 209 Libraries were sequenced on a Genome Analyzer IIx (Illumina, San Diego, California,

210 U.S.A.) in a 36 base single read multiplex run.

211

212 De novo assemblies

- Each sample was assembled using the CLC Genomics workbench V4.5
- 214 (<u>http://www.clcbio.com/</u>).
- 215 Standard parameter for read trimming and *de novo* assembly was used with one exception.
- 216 The similarity value was increased to 0.9. The average used read length of the quality
- trimmed reads was 35 bases. The minimal size for contiguous sequences (contigs) was set to
- 218 300 bp. In addition, all obtained data of each strain were assembled and used for individual
- 219 draft genome analysis in the following steps.
- 220
- 221 Taxonomical assignment
- 222 Contigs were compared via BLAST [Altschul et al., 1997] against NRPROT
- 223 (<u>ftp://ftp.ncbi.nlm.nih.gov/blast/db/</u>). BLASTX results were uploaded in MEGAN (MEta
- 224 Genome Analyzer) [Huson et al., 2011]. Contigs were handled as reads in MEGAN using a
- 225 coverage level of one. All sequences with an assignment to the phylum *Tenericutes* were
- selected for automated annotation [Rabus et al., 2002].
- 227
- 228 Calculation of enrichment
- 229 Enrichment was evaluated by read counts in two different approaches. First, the percentage of
- reads showing perfect matches (100% identity) on the chromosome sequence of the four
- complete genomes (AP006628.2, CP000061, CU469464, CU469464) was calculated. This
- was performed by megablast using a word length of 20 and subsequently filtering of the
- 233 output by a Perl script. Second, the percentage of phytoplasma assigned reads building
- contigs was calculated from the assembly.

- 236 *Draft genome annotation*
- 237 Contigs for each strain were obtained by the assembly of all read data and subsequent
- taxonomical selection as described above. Contigs were merged in a draft sequence but kept

separated by 100 Ns. The two drafts were analysed by the automated annotation pipeline

HTGA [Rabus et al., 2002] and manually curated in Artemis [Rutherford et al., 2000].

Annotated draft sequences were deposited in Genbank (strain 284/09 Acc. no. FO393427 and

242 strain 231/09 Acc. no. FO393428).

243

244 Expression of sucP gene in strain 284/09

Total RNA was prepared from tissue-cultured tobacco infected by 'stolbur' strain 284/09

246 using nucleoSpin RNA II extraction kit (Macherey-Nagel, Düren, Germany) following the

247 manufacturer's instructions and using a final elution volume of 50 µl. Eight microliters of

248 RNA was treated with one unit of DNase I (Thermo Scientific, Bremen, Germany). Aliquots

249 of 4.5 μl DNase treated RNA were used as template for amplification in RT-PCR and PCR

250 reactions to examine expression of *sucP* and absence of DNA, respectively. Primers sucP-left

251 (5'- AGTTTTTGCACCAGGCATTC -3') and sucP-right (5'-

252 GTGTGGGGGTTGTAATTTCG -3') were designed for amplification of partial *sucP*

sequence (expected product of 242 bp). RT-PCR assay with the sucP-left/right primer pair

254 was carried out on DNase treated RNA in 25 μL-scale RT-PCR reaction mix containing 4.5

255 μL template RNA, 1X OneStep RT-PCR buffer, 0.4 mM dNTP mix, 0.4 μM of each primer

and 1µl OneStep RT-PCR enzyme mix (Qiagen, Hildesheim, Germany).

257 PCR assays were carried out on DNase treated RNA and total DNA in a 25 µL-scale PCR

258 reaction mix containing 4.5 μL template RNA or 1 μL template DNA, 1× PCRMasterMix

259 (Thermo Scientific, Bremen, Germany) and 0.4 μ M of each primer. PCR negative control

260 reaction was set up without DNA.

261 Reverse transcription reaction was performed for 30 min at 50°C followed by 13 min initial

262 denaturation at 95°C. Subsequent PCR assay contains a denaturation step of 2 min at 94°C

and a three step PCR cycling (94°C, 30 sec; 57°C, 30 sec; 72°C, 1 min) repeated 35 times and

a final extension step of 5 min for 72° C. Amplification or absence and size of PCR products

were analyzed by agarose gel electrophoresis using 6 µl of RT-PCR or PCR products. 100 bp
and 1 kb DNA ladder were used for size comparison (Thermo Scientific, Bremen, Germany).

268 Comparative analysis of 'stolbur' strains

269 The two 'stolbur' draft sequences from Serbia were compared by BLASTN [Altschul et al., 270 1997] using strain 284/09 as reference. Calculation was performed using a word length of 300 271 and low complexity filter off. BLASTN-output was filtered for a minimal sequence identity of 272 99% and average alignment length was calculated by a Perl script. Conservation of deduced 273 protein content was estimated using the draft sequence of strain 284/09 as subject and the 274 deduced proteins of strain 231/09 as query in a TBLASTN comparison. In a second approach, 275 deduced proteins of the Serbian stolbur strains were compared via BLASTP. BLAST-outputs 276 were filtered for identity of 99% of the aligned regions by MSPcrunch [Sonnhammer and 277 Durbin, 1994]. Comparison on obtained data versus published 'stolbur' phytoplasma 278 determined in the study of Cimerman et al. (2006) was performed by BLASTP [Altschul et 279 al., 1997] and filtering the output by MSPcrunch [Sonnhammer and Durbin, 1994].

280

281 Limits of short read assemblies

282 The problems of the assembly of repeat-rich genomes resulting from short reads were

simulated by an *in silico* approach. Therefore, the chromosome sequences of 'Ca. P.

australiense' (acc. no. AM422018) and *Escherichia coli* strain K12 substr. MG1655 (acc. no.

285 U00096.2) were used as template for the ART simulation tool [Huang et al., 2012] to obtain

simulated Illumina read data sets. Single read data sets were calculated with a length of 35 b,

- 287 100 b and paired-end reads with (2x) 100 b covering the chromosomes 168-fold each. Reads
- were assembled (see above), total contig length (TCL) was calculated and contigs extracted.
- 289

290 Mapping on the chromosome of 'Ca. P. australiense'

291 Chromosome information on protein encoding sequences and potential pseudogenes of 'Ca. 292 P. australiense' were extracted from the genome (acc. no. AM422018). Potential multi-copy 293 genes were identified by BLASTClust (http://www.ncbi.nlm.nih.gov) also considering the 294 annotated pseudogenes, which are so far not experimentally validated. 'Ca. P. australiense' 295 contigs obtained from the assembly of simulated Illumina reads (ART approach see above) 296 were assigned to corresponding positions on its chromosome by BLASTN using a wordsize 297 of 100 b and subsequent filtering for a minimal identity of 99% by MSPcrunch. Deduced 298 protein coding sequences of the two Serbian 'stolbur' strains were assigned to potential 299 homologs of 'Ca. P. australiense' by BLASTP (e-value cut-off: 1e-15 and MSPcrunch 300 identity filter cut-off: 30%). First hit was considered in both analyses, if multiple hits show an 301 identical BLAST score. GC plot calculation and visualization of results was performed in 302 Artemis. 303

000

304

305 **Results and discussion**

306

307 *Obtained sequence data*

308 Sequencing by synthesis (SBS) was performed for nine barcoded libraries (one lane of the

flow-cell) resulting in 20,588,492 quality passed short-reads with an average length of 35

310 bases. Obtained read numbers/sample vary from 2,290,270-3,494,601 reads (Table 1). In

total, above 741 Mb of quality filter-passed sequence information was generated.

312 Experiments limited to Dellaporta enrichment approach and Phi29 amplification using

313 random hexamers for strain 284/09 and Phi29 amplification using random hexamers alone for

314 strain 231/09 resulted in short total contig length (TCL) of 211.6 kb and 7.6 kb, respectively.

315 Higher TCL was obtained in all Phi29 reactions supplemented by oligonucleotides (P1/P7 or

oligonucleotides based on calculated oligomers). Furthermore, a lower G + C content was
observed for the contigs derived from these experiments.

318 Percentages of reads assigned to phytoplasma containing contigs were calculated and an 319 enrichment was observed (Table 2). Supplementation by the calculated oligomers resulted in 320 a 2.3 and 2.4-fold increase of assigned phytoplasma reads and in a 2.2 and 5.9-fold increase of 321 the percentage of the phytoplasma assigned TCL for strain 284/09 and strain 231/09 322 respectively. A TCL of 460 and 439 kb was reached in these experiments (**Table 1**). Long 323 TCLs resulted from the high percentage (80-81%) of phytoplasma assigned reads allowing a 324 contig formation (Table 2). 325 The highest P1/P7 oligonucleotide concentration did not result in an enrichment increase 326 (Table 1 & 2). This may result from insufficient resuspension of the previously dried 327 oligonucleotides. Low P1/P7 oligonucleotide supplementation also shows no significant effect 328 compared to the usage of the hexamers without additional supplementation. These results can 329 be observed taking into account the increase of reads in contigs assigned to phytoplasma but 330 also by an independent calculation based on a simplified mapping of reads from this study on 331 the four complete phytoplasma genomes.

332

333 Strain data assemblies

334 Data obtained for each strain were pooled and assembled. The unselected metagenomic draft 335 sequence of the strain 284/09 plant sample reaches a length of 1,340 kb while 915 kb 336 sequence was obtained for the strain 231/09 infected sample. Draft sequences were organized 337 in 685 contigs for strain 284/09 and 739 contigs for strain 231/09 (minimal contig size 300 338 bp). The contig numbers result in 1,965 bp and 1,238 bp average contig length, respectively. 339 About 19% (128/685) of the contigs of strain 284/09 and 40% (298/739) of strain 231/09 340 could be assigned to phytoplasma (Table 3) using the MEGAN approach [Huson et al., 341 2011]. Below 1% of the initial contigs (assignment to the phylum *Tenericutes*) could not be

342 assigned to 'Ca. Phytoplasma' and were removed manually during the gene annotation. The 343 average contig length of the phytoplasma assigned sequences is increased with 4,356 bp (168-344 fold sequencing coverage) and 1,731 bp (34-fold sequencing coverage) compared to 345 unselected contigs and results from a lower plant background. The draft sequences show an 346 average identity of 99% to each other in aligned regions (above 457 kb). 347 The 448 (strain 284/09) and 346 (strain 231/09) protein coding genes were assigned as 348 completely determined. The shorter contig length in strain 231/09 results in a lower number 349 of complete genes and a higher number of partial genes. In addition, differences in the 350 completeness and quality are indicated by the number of 27 and 8 tRNAs encoded in the two 351 strains. However, successful application of this genomic draft approach can be estimated by the functional assignment made on 328 deduced complete proteins for strain 284/09 and 238 352 353 for lower covered strain 231/09. 452 of 573 deduced protein sequences of strain 231/09 are 354 also encoded in strain 284/09 showing an identity of above 99%. 355 A high portion of the 520 deduced proteins of 'stolbur' strain 284/09 can be also identified in 356 the protein data set of the completely determined chromosome of 'Ca. P. australiense'. 357 However, only one mapped protein of strain 284/09 shows 99% identity to 'Ca. P. 358 australiense' but 438 at least 80% identity. The data set from 'stolbur' PO generated by SSH 359 approach produced 194 deduced protein sequences [Cimerman et al., 2006]. 186 potential 360 orthologs were identified in strain 284/09 showing an identity of at least 30%; 80 of the 361 identified proteins show an identity of 99%.

362

363 Analysis of the genomic core of 'stolbur' strains 284/09 and 231/09

364 Complete gene sets encoding proteins for replication, DNA modification and structure and

365 DNA repair were identified in both genomes [Kube et al., 2012]. Both strains encode the

366 excision repair complex *uvrABC* comparable to the one of '*Ca*. P. asteris' strains OY-M and

367 AY-WB and 'Ca. P. australiense', this latter belongs to the same phylogenetic branch. Results

368 support the separated evolutionary genome condensation of '*Ca*. P. mali' that is lacking these369 genes.

370 Furthermore, the gene content necessary for transcription was identified in both draft 371 sequences. Differences in the gene content due to the level of completeness of drafts are 372 visible in the gene sets involved in translation, e.g. for ribosomal genes. The draft of strain 373 284/09 contains the complete set of ribosomal genes, while the draft of strain 231/09 lacks six 374 genes (*rplJ*, *rpmF*, *rpmH*, *rpmI*, *rpsL* and *rpsN*). It was possible to identify all tRNA 375 synthetases in the draft of strain 284/09, while it was impossible to identify the genes for 376 prolyl-tRNA and lysidine-tRNA synthetase in strain 231/09. 377 The conserved content of membrane-associated genes was identified in both draft sequences 378 including the associated gene set assigned to lipid synthesis [Kube et al., 2012]. Common 379 ABC-transporters for the ATP-dependent putative import of manganese/zinc, cobalt, 380 spermidine/putrescine, sugars or putative glycerol-3-phosphate, oligopeptides and methionine 381 are encoded in the sequencing obtained. Furthermore, a putative thiamine transporter of the 382 ThiA/YuaJ family was identified. Both strains also share the content of multidrug efflux 383 pumps (MdlA/B, NorM), P-type ATPases and the large-conductance mechanosensitive 384 channel protein with the other sequenced phytoplasmas. 385 The prominent membrane proteins Vmp1 and Stamp (Amp) of 'stolbur' were identified in 386 both draft sequences. Both proteins are supposed to be involved in phytoplasma-host 387 interaction [Cimerman et al., 2009; Fabre et al., 2011]. StamP is supposed to show a 388 conserved sequence synteny with the order *groEL-amp-nadE* in several phytoplasma genomes 389 [Fabre et al., 2011] but not in 'Ca. P. mali' (acc. no. CU469464). This synteny was also 390 identified in the two strains examined in this study. This is in agreement with the identity of 391 91% reached in the alignment of strain 284/09 and strain 231/09 of StamP and VmP1 from 392 stolbur phytoplasma [Fabre et al., 2011].

In both 'stolbur' strains, gene sets necessary to build the general Sec-dependent pathway in
phytoplasma were identified (*ffh*, *ftsY*, *secA*, *secE*, *secY*) except for *yidC*, which was not
identified in strain 231/09.

396 The energy metabolism encode the Embden-Meyerhof-Parnas pathway [Oshima et al., 2004] 397 and the suggested alternative pathway from malate (or a similar substrate) to acetate [Kube et 398 al., 2012]. In consequence, the genes encoding the upper part of the glycolysis were identified 399 (phosphoglucose isomerase, Pgi; phosphofructo-kinase, PfkA; fructose-biphosphate aldolase, 400 Fba; triosephosphate isomerase, TpiA). In contrast to 'Ca. P. mali' but in agreement with the 401 other fully sequenced phytoplasmas, the genes encoding proteins involved in the energy 402 yielding part were also identified (glyceralaldehyde-phosphate dehydrogenase, GapA; 403 phosphoglycerate mutase, Pgm; enolase, Eno; pyruvate kinase, PykF). The suggested 404 alternative energy-yielding pathway encoded in all four completely determined genomes of 405 phytoplasma strains is also encoded by 'stolbur' strains from Serbia [Kube et al., 2012]. It 406 encodes the steps of malate uptake (symporter MleP), oxidative decarboxylation (SfcA), 407 generation of Acetyl-CoA by the pyruvate dehydrogenase multienzyme complex (AcoAB, 408 AceF, Lpd), formation of Acetyl-phosphate by the suggested phosphotransferase (PduL-like protein) and acetate (AckA) including the gain of one ATP [Kube et al., 2012]. In contrast to 409 410 this second pathway, glycolysis is dependent on the supply of a phosphorylated hexose at the 411 beginning. The option of a direct uptake of trehalose-6-phosphate or sucrose-6-phosphate and 412 subsequent processing with respect to the particular environment of phytoplasmas has to be 413 taken into consideration [Kube et al., 2012]. Indeed, no hints for an encoded membrane bound 414 phosphoenolpyruvate-dependent phosphotransferase system (PTS) were provided for 415 phytoplasmas so far and it remains still unclear how phytoplasmas perform this step. A 416 phosphoenolpyruvate-dependent PTS activity was shown for *Mycoplasma gallisepticum*, M. 417 mycoides subsp. mycoides and M. mycoides subsp. capri but not for Acholeplasma laidlawii

418 [Cirillo and Razin, 1973]. The last finding might be remarkable because *Acholeplasma* are
419 paraphyletic to the genus '*Ca*. Phytoplasma' [Gundersen et al., 1994].

420 However, both 'stolbur' strains encode a truncated sucrose phosphorylase (SucP). Sequence 421 comparison of *sucP* and flanking sequences show 100% identity on nucleotide sequence. 422 Sucrose may be taken up by some phytoplasmas from the phloem sap via a sugar ABC-423 transporter [Kube et al., 2012] or may be a permease [Reid and Abratt, 2005]. The sucP gene 424 is encoded between a Zinc-dependent protease (TldD) and a multidrug efflux pump (NorM) 425 in both strains. SucP mediates the generation of alpha-D-glucose-1-phosphate and beta-D-426 fructofuranose from sucrose and to a lesser extent hydrolysis glucose-1-phosphate [van den 427 Broek et al., 2004]. While TldD and NorM protein show highest similarities to phytoplasmas, 428 SucP shows its lowest e-values in BLASTP against NRPROT to Leuconostoc mesenteroides (e-value 6e⁻⁸⁷; acc. no. ABW71903) followed by members of the genus *Lactobacillus* (e-value 429 6e⁻⁸⁴; refseq acc. no. NC_009513.1). Proteins show a high identity of around 70% to the SucP 430 431 of strain 284/09. The deduced protein length of 485-491 aa significantly differs from the SucP 432 of the two Serbian 'stolbur' strains (136 aa). SucP is also encoded in 'Ca. P. australiense' 433 (annotated as GtfA) and 'Ca. P. asteris' strain OY-M. While it might be also truncated in 434 strain OY-M, 'Ca. P. australiense' encodes the putative full-length protein. It was impossible 435 to detect this protein in 'Ca. P. asteris' strain AY-WB or in 'Ca. P. mali' genomes. The coding 436 and truncation of *sucP* in phytoplasmas is remarkable because sucrose represents the most 437 prominent sugar in the phloem sap [Vanhelden et al., 1994]. Surprisingly, expression of sucP 438 is confirmed for strain 284/09 by RT-PCR (Figure 2). One may speculate, if the truncated 439 sucP lost its original function. However, the subsequent processing remains unclear because 440 alpha-D-glucose-1-phosphate has to be converted to alpha-D-glucose-6-phosphate by the 441 phosphoglucomutase (PgmA). Such an alpha-D-phosphohexomutase is encoded in 442 Acholeplasma laidlawii strain PG-8A (acc. no. YP_001620839) and in several mycoplasmas

but is not identified in phytoplasmas so far. This might also be due to the weak genomicdatabase for phytoplasmas.

445 This little shunt that would allow phytoplasmas to (I) metabolize the most prominent sugar in 446 phloem sap, (II) overcome the lack of a PTS system and (III) provide a needed entry enzyme 447 of the upper part of the glycolysis. It is likely that the ancestors of the phytoplasmas were able 448 to use this shunt for the degradation of sucrose or a similar disaccharide. Furthermore, it 449 raises the question, if the other prominent disaccharide trehalose of the insect vectors was 450 utilized in a similar manner by phytoplasmas. Phytopathogenic spiroplasmas perform such a 451 switch from glucose and fructose in the plant to trehalose in the hemolymph of the leafhopper 452 vector [Gasparich, 2010; Gaurivaud et al., 2000].

453

454 Reached genome coverage using short reads for assembly

455 No estimation is made on the completeness of the draft genomes of the examined 'stolbur' 456 strains. The complete genome of the related 'Ca. P. australiense' is heavily characterized by 457 repeats covering 24% of the sequence [Tran-Nguyen et al., 2008]. There is a risk of 458 misassemblies due to the shared high similarity within the individual repeat groups. Conflicts 459 occurring during the assembly of these regions result in rejection of reads from the assembly. 460 It is likely that several repetitive elements are encoded in both strains. Identification of 461 transposases (3 proteins in strain 284/09 and 1 in strain 231/09) and a group II intron reverse 462 replicase (5 proteins in strain 284/09 and 3 in strain 231/09) support such an estimation for 463 both samples.

A simulation based on the chromosome sequence of '*Ca*. P. australiense' with a length of 879,959 bp was performed calculating Illumina read sets with a size of 35, 100 and paired reads of 2x 100 nucleotides using ART simulation tools [Huang et al., 2012]. None of the performed *de novo* assemblies using the simulated read sets reached chromosome length (single read length 35 b: 586 kb; single read length 100 b: 596 kb; paired-end reads length

469 100 b each: 616 kb). Contigs with a size of at least 300 b cover 67-70% of the chromosome. 470 Misassemblies and conflicts resulting from repeats have a major impact on results. This is 471 supported by a mapping of the 586 kb reached by the assembly of simulated reads from 'Ca. 472 P. australiense' on the chromosome in comparison to the location of potential pseudogenes 473 and multi-copy genes (Figure 3). However, simulated assemblies show a sequence identity of 474 99% to the reference chromosome providing an estimation of the quality and usability of 475 sequences of such a genomic draft. There is a high probability that also the obtained 476 assemblies of the Serbian 'stolbur' strains show a similar problematic taking into account the 477 distribution of the deduced proteins by mapping on 'Ca. P. australiense'. 478 In comparison, assemblies based on read-simulation performed on the comparable repeat-479 poor 4,640 kb large E. coli strain K12 substr. MG1655 chromosome resulted in a similar 480 chromosome length covering 97-98% considering contigs with a minimal length of 300 bp 481 (single read length 35 b, TCL 4,518 kb; single read length 100 b: 4,532 kb; paired-end reads 482 length 100 b each: 4,543 kb). 483 In conclusion, a direct estimation on completeness of the genomic draft of phytoplasmas 484 appears to be risky: sequence quality of assembled regions is expected to show high 485 confidence but usage of potential multi-copy genes for on-going studies directly from draft

487

486

488 Other phytoplasma draft approaches

sequences is limited and needs additional evaluation.

489 Starting on a DNA template resulting from isothermal amplification, a short read sequencing 490 approach was successfully used for the determination of two 'stolbur' draft genome 491 sequences. It is shown that it is possible to generate phytoplasma genomic draft sequence 492 from below a gram of starting material using low costs sequencing chemicals and comparable 493 little hand on time. The presented first results of enrichment by group-assigned primers of 494 target DNA in a metagenomic sample are basic for other studies. No plasmids were detected

in this study but it is likely that plasmid-containing templates are risky for such an approach[Tran-Nguyen and Gibb, 2007].

497 A higher number of premade assumptions are made by Firrao and colleagues 498 providing four genomic draft sequences of phytoplasmas in a recently published study 499 [Saccardo et al., 2012]. Major differences in the initial steps are the usage of a higher amount 500 of starting material (10 µg of DNA) and no amplification prior to sequencing library 501 construction. Finally assigned phytoplasma data were obtained by a coverage based selection 502 of contigs and reads respectively, negative selection against a non-infected host plant data set 503 and screening of contigs resulting from the selected read assembly against phytoplasma 504 sequences in public databases. Phytoplasma drafts derived from the colonized model plant 505 Catharanthus roseus reached TCL from 584-648 kb resulting from contigs with an average 506 length of 2.3-3.7 kb of these samples. The draft sequence of an Italian strain of clover 507 phyllody phytoplasma showing a higher level of colonization in C. roseus reached the highest 508 percentage of assigned phytoplasma reads with 12% while the other samples reached only 3-509 6%. In comparison, none of the 'stolbur' templates reached more than 2.1% of assigned reads 510 in our study and the non-amplified templates reached 0.8-0.9 % (Table 2). However, the 511 higher sequencing coverage for 'stolbur' strain 284/09 (168-fold) resulted in an expected 512 higher average contig size 4.4 kb. The strain 231/09 shows a decreased average contig length 513 with 1.7 kb corresponding to 34-fold sequencing coverage and the usage of short reads (36 b) 514 compared to the 100 b reads used in the study of Firrao and colleagues [Saccardo et al., 2012]. 515 A high sequencing coverage for on-going *de novo* sequencing projects has to be anticipated in 516 general because a shorter average contig length drastically influences the number of partial 517 gene sequences in a draft (Table 3) and thereby the overall quality of the genomic draft.
